Desirable: Less than 200 mg/dl
 Borderline High Risk: 200 to 239 mg/dl
 High Risk: 240 mg/dl and over, on repeated values

Optimal Level for Cardiac Patients: Less than 200 mg/dl

HDL-C: High HDL has generally been found to be protective, decreasing the risk of coronary artery disease (CAD) in most people. However, some recent studies have shown that in some people with high HDL, the HDL is not protective and may, in fact result in higher risk for CAD than in people with normal HDL levels. In one study it was shown that people with CAD and high HDL had underlying genetic anomalies in enzymes important in lipid turnover. Another study showed that high levels of abnormally large HDL particles were associated with increased risk of CAD. Factors that elevate HDL concentrations include chronic alcoholism, treatment with oral estrogen replacement therapy, extensive aerobic exercise, and treatment with niacin, statins, or fibrates. Smoking reduces levels of HDL cholesterol, while quitting smoking leads to a rise in the plasma HDL level.
