EXPECTED VALUES :-

Metabolically healthy patients	=	4.8 - 5.5 % HbA1C
Good Control	=	5.5 - 6.8 % HbA1C
Fair Control	=	6.8 - 8.2 % HbA1C
Poor Control	=	>8.2 % HbA1C

REMARKS:-

In vitro quantitative determination of HbA1C in whole blood is utilized in long term monitoring of glycemia

The HbA1C level correlates with the mean glucose concentration prevailing in the course of the patient's recent history (approx - 6-8 weeks) and therefore provides much more reliable information for glycemia monitoring than do determinations of blood glucose or urinary glucose.

It is recommended that the determination of HbA1C be performed at intervals of 4-6 weeks during Diabetes Mellitus therapy.

Results of HbA1C should be assessed in conjunction with the patient's medical history, clinical examinations and other findings.

REMARKS:

In diabetes, involvement of the kidney can result in persistent proteinuria (Kimmelstein-Wilson Syndrome, Diabetic Intercapillary Glomerulosclerosis). Microalbuminuria is proteinuria that is above normal but which is below the level detected by urine dipsticks. Diabetic patients with microalbuminuria tend to have progression of their disease with cardiovascular and end-stage renal complications.

Interpretation:

normal: < 0.01

microalbuminuria: 0.02 to 0.2

nephropathy: > 0.2

a ratio ≥ 3.5 correlates with an albumin excretion rate of ≥ 30 g/minute

Note: TSH levels are subject to circadian variation, rising several hours before the onset of sleep, reaching peak levels between 11 pm to 6 am. Nadir concentrations are observed during the afternoon. Diurnal variation in TSH level approximates $\pm 50\%$, hence time of the day has influence on the measured serum TSH concentration.
