Comment:

Creatinine estimation is done to assess kidney function. It is not dependent on dietary factors. Normal values are obtained in kidney diseases, except in advanced renal failure and therefore its estimation is more valuable if coupled with clearance.

Critical value is > 4 mg/dL (indicate severe renal disease).

Interfering factors :

Ascorbic acid can increase creatinine level.

A diet high in protein like meat can increase the level.

Note : All investigations have their own limitation which are imposed by the limits of sensitivity and specificity of individual assay procedures as well as the specimen received by the laboratory. Isolated laboratory investigations never confirm the diagnosis of the diseases. They only help in arriving at a diagnosis in conjunction with clinical presentation and other related investigations.
