REMARKS :

In vitro quantitative determination of **HbA1c** in whole blood is utilized in long term monitoring of glycemia. The HbA1c level correlates with the mean glucose concentration prevailing in the course of the patient's recent history (approx - 8-12 weeks) and therefore provides much more reliable information for glycemia monitoring than determination of blood glucose or urinary glucose. It is recommended that the determination of **HbA1c** be performed at intervals of 3-6 months during diabetes mellitus therapy. Results of **HbA1c** should be assessed in conjunction with the patient's medical history, clinical examinations and other findings.

Estimated average glucose (eAG) - There is a predictable relationship between HbA1c and eAG. It helps people with diabetes to correlate their A1c to daily glucose monitoring levels. It reflects the average glucose levels in the past 2-3 months. The eAG calculation converts the A1c percentage to the same units used by glucometers mg/dl. The following table shows the relationship of eAG and A1c.

HbA1c	eAG (mg/dl)

The new recommendations for TSH levels during pregnancy are the following:

First trimester: less than 2.5 with a range of 0.1-2.5.

Second trimester: 0.2-3.0

Note : TSH levels are subject to circadian variation, reaching peak levels between 2-4 am and at a minimum 6-10 pm
The variation is of the order of 50%, hence time of the day has influence on the measured TSH concentrations.
